SHARP LARGE DEVIATIONS FOR THE ORNSTEIN-UHLENBECK PROCESS

Доказывается точный принцип больших уклонений для хорошо известных случайных величин, ассоциированных с процессом Орнштейна–Уленбека, таких, как энергия, оценка максимального правдоподобия параметра сноса и логарифмическое отношение правдоподобия.

Ключевые слова и фразы: большие уклонения, процесс Орнштейна–Уленбека, оценка правдоподобия.

1. Introduction

Consider the Ornstein–Uhlenbeck process

$$dX_t = \theta X_t dt + dW_t, \quad (1.1)$$

where W is a standard Brownian motion and the parameter θ is strictly negative. For the sake of simplicity, we choose the initial state $X_0 = 0$. In this paper, we investigate the sharp large deviation properties for well-known random variables associated with (1.1) such as the energy

$$S_T = \int_0^T X_t^2 dt, \quad (1.2)$$

the maximum likelihood estimator of θ

$$\hat{\theta}_T = \frac{\int_0^T X_t dX_t}{\int_0^T X_t^2 dt} = \frac{X_T^2 - T}{2 \int_0^T X_t^2 dt}, \quad (1.3)$$

and the log-likelihood ratio

$$V_T = (\theta_0 - \theta_1) \int_0^T X_t dX_t - \frac{1}{2} (\theta_0^2 - \theta_1^2) \int_0^T X_t^2 dt \quad (1.4)$$

with θ_0 and θ_1 strictly negative. It was already proven that a.s., as T goes to infinity

$$\frac{S_T}{T} \longrightarrow -\frac{1}{2\theta}, \quad \hat{\theta}_T \longrightarrow \theta, \quad \frac{V_T}{T} \longrightarrow -\frac{(\theta_0 - \theta_1)^2}{4\theta_0}. \quad (1.5)$$

Fluctuations are also known [1]. More recently, Bryc and Dembo [8] and Florens-Landaïs and Pham [14] have established large deviation principles for S_T and $\hat{\theta}_T$. Strictly speaking, $\hat{\theta}_T$ is not the maximum likelihood estimator of θ since $\hat{\theta}_T$ may take nonnegative values whereas the parameter θ is assumed to be strictly negative. Nevertheless, we use this terminology through the paper. We present here sharp large deviation principles for the random variables S_T , $\hat{\theta}_T$ and V_T . As usual, we shall say that a family of real random variables (Z_T) satisfies a Large Deviation Principle (LDP) with rate function I , if I is a lower semicontinuous function from $\mathbf{R}$ to $[0, +\infty]$ such that, for any closed set $F \subset \mathbf{R}$, $\limsup_{T \rightarrow \infty} T^{-1} \log \mathbf{P}\{Z_T \in F\} \leq -\inf_{x \in F} I(x)$, while for any open set $G \subset \mathbf{R}$

$$-\inf_{x \in G} I(x) \leq \liminf_{T \rightarrow \infty} \frac{1}{T} \log \mathbf{P}\{Z_T \in G\}.$$

Moreover, I is a good rate function if its level sets are compact subsets of $\mathbf{R}$. When I has a unique minimum m , which will always be the case here, an LDP for (Z_T) gives the asymptotic behavior of $\mathbf{P}\{Z_T \geq c\}$ or $\mathbf{P}\{Z_T \leq c\}$ in a logarithmic scale whenever $c > m$ or $c < m$, respectively. We shall say that a sequence of real random variables (Z_T) satisfies a Sharp Large Deviation Principle (SLDP) if, for any real number c , it is possible to give asymptotic expansions of $e^{TI(c)}\mathbf{P}\{Z_T \geq c\}$ or $e^{TI(c)}\mathbf{P}\{Z_T \leq c\}$ in powers of T^{-1} . For the sake of simplicity, we present only the first one.

In order to prove an LDP for (1.2), (1.3) or (1.4), the main tool is the normalized cumulant generating function (c.g.f.) of the pair $(\int_0^T X_t dX_t, \int_0^T X_t^2 dt)$

$$\mathcal{L}_T(a, b) = \frac{1}{T} \log \mathbf{E}[\exp(\mathcal{Z}_T(a, b))], \quad (1.6)$$

where, for any $(a, b) \in \mathbf{R}^2$,

$$\mathcal{Z}_T(a, b) = a \int_0^T X_t dX_t + b \int_0^T X_t^2 dt. \quad (1.7)$$

It is possible to establish SLDP for all linear combinations of $\int_0^T X_t dX_t$ and $\int_0^T X_t^2 dt$. However, in order to improve the presentation of the paper, we prefer to focus our attention on the random variables (1.2), (1.3) and (1.4).

In discrete time, the analog of (1.1) is the first order autoregressive process. It was studied, as a particular case, in [4] for LDP and [5] for SLDP. The proofs used Toeplitz matrices and their asymptotic spectral properties given by the first Szegő theorem for LDP and the strong Szegő theorem for SLDP.

The covariance of the stationary Ornstein–Uhlenbeck process is a Wiener–Hopf operator and for some «quadratic forms», we can use a similar scheme [23]. Here, we take advantage of the explicit expression of the c.g.f.

An important point for proving an LDP is the determination of the domain Δ of the limit $\mathcal{L}$ of the c.g.f. We shall say that $\mathcal{L}$ is steep if its

derivative has an infinite limit at the boundary of Δ (see, e.g., [9, p. 44]). It is a sufficient condition to apply the Gärtner–Ellis theorem. The main difficulty arises when $\mathcal{L}$ is not steep.

Before entering into details of the different cases, let us summarize the general scheme. We have to study probabilities of the form $\mathbf{P}\{\mathcal{Z}_T(a, b) > zT\}$. We follow a similar approach to the one recently given in [5] for discrete time quadratic forms of Gaussian stationary processes. It was inspired by the original work of Bahadur and Rao [2] for the sample mean of a sequence of i.i.d. random variables. We perform an exponential change of probability of parameter φ to be chosen to «track» z ,

$$\frac{d\mathbf{Q}_T}{d\mathbf{P}} = \exp\left(\varphi\mathcal{Z}_T(a, b) - T\mathcal{L}_T(a\varphi, b\varphi)\right). \quad (1.8)$$

Then, we have the decomposition

$$\mathbf{P}\{\mathcal{Z}_T(a, b) > zT\} = A_T B_T$$

with

$$A_T = \exp\left[T(\mathcal{L}_T(a\varphi, b\varphi) - z\varphi)\right], \quad (1.9)$$

$$B_T = \mathbf{E}_T\left(\exp[-\varphi(\mathcal{Z}_T(a, b) - zT)] \mathbb{I}_{\mathcal{Z}_T(a, b) \geq zT}\right), \quad (1.10)$$

where $\mathbf{E}_T$ is the expectation under $\mathbf{Q}_T$. On the one hand, an asymptotic expansion for A_T is given in Section 2. On the other hand, we expand B_T via an evaluation of the characteristic function Φ_T of $(\mathcal{Z}_T(a, b) - zT)$ (properly normalized) under the new probability $\mathbf{Q}_T$. In general, Φ_T has a pointwise limit. This is however not enough to study B_T . Actually, we obtain a complete expansion of Φ_T similar to the one established in the i.i.d. case by Cramer [7] and Esseen [12] and we integrate it using Parseval's theorem. This approach was developed in other contexts with different asymptotics by Ben Arous [3], Bolthausen [6], Dembo, Mayer-Wolf and Zeitouni [11], Ibragimov [16], Li [19] and Zolotarev [24] (see also the references therein).

In the steep case, the limit distribution is $N(0, 1)$ and the convergence of Φ_T is dominated. Thus, we get an SLDP similar to the one obtained in discrete time [5]. In particular, for $c > -1/(2\theta)$, we prove that $\sqrt{T} e^{TI(c)} \mathbf{P}\{S_T \geq cT\}$ has a limit given explicitly.

In the non steep case, occurring only for (1.3), we find new regimes. For $c \geq \theta/3$, the rate function I is linear. In the change of probability (1.8), we are brought to use a time varying parameter φ_T . This strategy was developed in [10] and [8]. Under this new probability, for $c > \theta/3$, the limit distribution is a centered χ^2 (see also [14]). To establish an SLDP, this gives rise to a new problem since uniform integrability is not guaranteed. Eventually, the SLDP has the same form that in the steep case but with different constants. For $c = \theta/3$, φ_T tends to the boundary of Δ at a different rate and the limit distribution is the convolution of an $N(0, 1)$ and a centered χ^2 . This yields

an SLDP with rate $\sqrt{T}$ instead of T . In particular, $T^{1/4}e^{TI(c)}\mathbf{P}\{\hat{\theta}_T \geq c\}$ has a limit given explicitly.

The paper is organized as follows. In Section 2, we give a sharp description of $\mathcal{L}_T(a, b)$ and $\mathcal{Z}_T(a, b)$. Then, we present the SLDP results: Section 3 is devoted to the energy, Section 4 to the maximum likelihood estimator and Section 5 to the log-likelihood ratio. Proofs are collected in Sections 6 and 7.

2. Main tools

Before precisising specific results for each functional, we give two lemmas which are the core of all proofs and allow unified notation.

The convergence of (1.6) was studied in [14]. The following Lemma 2.1 gives a new presentation enlightening the role of the limit $\mathcal{L}$ and of the first order term $\mathcal{H}$ both for LDP and SLDP. This decomposition is completely analogous to the one given in discrete time [5].

It is well known that c.g.f. of quadratic functionals of Gaussian processes are connected to empirical distributions of eigenvalues of some operator (see, e.g., [15, Chapter 11]).

In our case, Lemma 2.2 gives a decomposition of $\mathcal{Z}_T$ using eigenvalues (see Section 7.1 for the operator) and a convergence of their empirical distribution. This last part is similar to the first Szegő theorem and uses the convergence of $\mathcal{L}_T$ to $\mathcal{L}$ for its proof.

The limit is proportional to the image of the Lebesgue measure by the spectral density of the stationary Ornstein–Uhlenbeck process of parameter $\theta < 0$

$$g(x) = \frac{1}{\theta^2 + x^2}$$

associated with the covariance $r(t) = -\exp(\theta|t|)/(2\theta)$.

Lemma 2.1. *Set $\Delta = \{(a, b) \in \mathbf{R}^2 \mid \theta^2 - 2b > 0 \text{ and } \theta + a < \sqrt{\theta^2 - 2b}\}$ and let $\rho(b) = \sqrt{\theta^2 - 2b}$.*

i) *For all $(a, b) \in \Delta$, we have*

$$\mathcal{L}_T(a, b) = \mathcal{L}(a, b) + \frac{\mathcal{H}(a, b)}{T} + \frac{1}{T} \mathcal{R}_T(a, b) \quad (2.1)$$

with

$$\begin{aligned} \mathcal{L}(a, b) &= -\frac{1}{2} (a + \theta + \rho(b)), \\ \mathcal{H}(a, b) &= -\frac{1}{2} \log \left(\frac{1}{2} \left(1 - (a + \theta) \rho^{-1}(b) \right) \right), \end{aligned} \quad (2.2)$$

$$\mathcal{R}_T(a, b) = -\frac{1}{2} \log \left(1 + \frac{1 + (a + \theta) \rho^{-1}(b)}{1 - (a + \theta) \rho^{-1}(b)} e^{-2T\rho(b)} \right). \quad (2.3)$$

ii) *Moreover, the remainder $\mathcal{R}_T(a, b)$ goes exponentially fast to zero:*

$$\mathcal{R}_T(a, b) = \mathcal{O}(e^{-2T\rho(b)}). \quad (2.4)$$

Denote by $\mathcal{F}$ the class of all continuous functions f on $\mathbf{R}$ such that $f(x) = xh(x)$ with h continuous.

Lemma 2.2. i) *There exists a sequence of real numbers (λ_j^T) such that $(\lambda_j^T) \in l^1(\mathbf{N})$,*

$$\mathcal{L}_T(a, b) = -\frac{aT}{2} + \sum_{j=1}^{\infty} \lambda_j^T \varepsilon_j^2, \quad (2.5)$$

where (ε_j) are independent standard $N(0, 1)$ random variables.

ii) *There exists a fixed compact $[A, B]$ such that $\lambda_j^T \in [A, B]$ for every j and T .*

iii) *If $b \neq 0$, then the empirical measure*

$$\nu_T = \frac{1}{T} \sum_{j=1}^{\infty} \delta_{\lambda_j^T} \quad (2.6)$$

converges for the duality with functions in $\mathcal{F}$ to ν defined, for any continuous function h with compact support, by

$$\langle \nu, h \rangle = \frac{1}{2\pi} \int_{\mathbf{R}} h(bg(x)) dx. \quad (2.7)$$

R e m a r k s. 1) The sequence (λ_j^T) is finite if $b = 0$ and infinite otherwise.

2) The case $a = 0$ is already known. Fix $b = 1$ to simplify. The Karhunen–Loève expansion of the process (X_t) gives directly i). Bryc and Dembo [8] proved ii) and iii) (see also [15, Chapters 8 and 11]). In this case, $A = 0$ and $B = \theta^{-2}$.

3) If a and b are both nonnegative (respectively nonpositive), all the (λ_j^T) are nonnegative and we may take $A = 0$ (respectively $B = 0$).

4) In the particular case of the likelihood ratio (1.4), decomposition (2.5) is well known (see, e.g., [18] and [22]).

W a r n i n g. The functions I , L , L_T , given in the following sections, are different. They are defined at the beginning of each section. In order to avoid heaviness in the notation, we choose to keep the same symbol for quantities of the same nature.

3. Energy

The LDP for (S_T) was proven by Bryc and Dembo [8] for general centered stationary Gaussian processes. In the particular case of the Ornstein–Uhlenbeck process (1.1), they have the following result.

Lemma 3.1. *$(T^{-1} S_T)$ satisfies an LDP with good rate function*

$$I(c) = \begin{cases} \frac{(2\theta c + 1)^2}{8c} & \text{if } c > 0, \\ +\infty & \text{otherwise.} \end{cases} \quad (3.1)$$

The rate function I has a unique minimum in $c = -1/(2\theta)$ which is the a.s. limit given in (1.5). We are going to improve this result by an SLDP for (S_T) similar to the well-known Bahadur–Rao theorem [2]. Set, for all $a < \theta^2/2$,

$$L(a) = \mathcal{L}(0, a) \quad \text{and} \quad H(a) = \mathcal{H}(0, a). \quad (3.2)$$

One can remark that the rate function I given by (3.1) is the Fenchel–Legendre dual of the function L .

Theorem 3.1. *$(T^{-1}S_T)$ satisfies an SLDP associated with L and H . More precisely, for all $c > -1/(2\theta)$, there exists a sequence $(b_{c,k})$ such that, for any $p > 0$ and T large enough,*

$$\mathbf{P}\{S_T \geq cT\} = \frac{e^{-TI(c)+H(a_c)}}{\sigma_c a_c \sqrt{2\pi T}} \left[1 + \sum_{k=1}^p \frac{b_{c,k}}{T^k} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right) \right] \quad (3.3)$$

with

$$a_c = \frac{4\theta^2 c^2 - 1}{8c^2}, \quad H(a_c) = -\frac{1}{2} \log \left(\frac{1}{2} (1 - 2\theta c) \right), \quad (3.4)$$

and $\sigma_c^2 = L''(a_c) = 4c^3$. The coefficients $b_{c,1}, b_{c,2}, \dots, b_{c,p}$ may be explicitly given as functions of the derivatives of L and H at point a_c . For example, the first coefficient $b_{c,1}$ is given by

$$b_{c,1} = \frac{1}{\sigma_c^2} \left(-\frac{h_2}{2} - \frac{h_1^2}{2} + \frac{l_4}{8\sigma_c^2} + \frac{l_3 h_1}{2\sigma_c^2} - \frac{5l_3^2}{24\sigma_c^4} + \frac{h_1}{a_c} - \frac{l_3}{2a_c \sigma_c^2} - \frac{1}{a_c^2} \right) \quad (3.5)$$

with $l_k = L^{(k)}(a_c)$ and $h_k = H^{(k)}(a_c)$. More precisely,

$$b_{c,1} = \frac{-2c(12\theta^4 c^4 + 12\theta^3 c^3 + 35\theta^2 c^2 + 4\theta c + 2)}{(4\theta^2 c^2 - 1)^2}. \quad (3.6)$$

4. Maximum likelihood estimator

Florens-Landaïs and Pham [14] have proven the following LDP for $(\hat{\theta}_T)$.

Lemma 4.1. *$(\hat{\theta}_T)$ satisfies an LDP with good rate function*

$$I(c) = \begin{cases} -\frac{(c - \theta)^2}{4c} & \text{if } c < \frac{\theta}{3}, \\ 2c - \theta & \text{otherwise.} \end{cases} \quad (4.1)$$

The rate function I has a unique minimum in $c = \theta$ which is the a.s. limit given in (1.5). The large deviation properties of $(\hat{\theta}_T)$ are related with the ones of

$$Z_T(c) = \int_0^T X_t dX_t - c \int_0^T X_t^2 dt \quad (4.2)$$

with $c \in \mathbf{R}$ since $\mathbf{P}\{\hat{\theta}_T \geq c\} = \mathbf{P}\{Z_T(c) \geq 0\}$. One has to keep in mind that the threshold c for $\hat{\theta}_T$ appears like a parameter for $Z_T(c)$. As before, we also

improve Lemma 4.1 by an SLDP for $(\hat{\theta}_T)$. Define $\Gamma = \{a \in \mathbf{R} \mid \theta^2 + 2ac > 0 \text{ and } \theta + a < \sqrt{\theta^2 + 2ac}\}$ and set, for all $a \in \Gamma$

$$L(a) = \mathcal{L}(a, -ca) \quad \text{and} \quad H(a) = \mathcal{H}(a, -ca). \quad (4.3)$$

The rate function I given by (4.1) is $I(c) = -\inf_a L(a)$. It is easy to check that

$$\Gamma = \begin{cases} \left[-\infty, -\frac{\theta^2}{2c} \right] & \text{if } c \leq \frac{\theta}{2}, \\ \left] -\infty, a^c \right[& \text{if } \frac{\theta}{2} < c \leq 0, \\ \left[-\frac{\theta^2}{2c}, a^c \right] & \text{if } c > 0 \end{cases} \quad (4.4)$$

with $a^c = 2(c - \theta)$. The main difficulty comparing with the previous section is that L is not always steep. Actually, for all $a \in \Gamma$

$$L(a) = -\frac{1}{2} \left(a + \theta + \sqrt{\theta^2 + 2ac} \right), \quad L'(a) = -\frac{1}{2} \left(1 + \frac{c}{\sqrt{\theta^2 + 2ac}} \right). \quad (4.5)$$

Consequently, for $c \leq \theta/2$, L is steep while this is no longer true for $c > \theta/2$ since $L'(a^c) = -\frac{1}{2}((3c - \theta)/(2c - \theta))$. Moreover, $L'(a) = 0$ if and only if $a = a_c$ with $a_c = (c^2 - \theta^2)/(2c)$ and $a_c \in \Gamma$ only when $c < \theta/3$. Therefore, $I(c) = -L(a_c)$ if $c < \theta/3$ and $I(c) = -L(a^c)$ otherwise.

Theorem 4.1. $(\hat{\theta}_T)$ satisfies an SLDP associated with L and H . More precisely, for all $\theta < c < \theta/3$, there exists a sequence $(b_{c,k})$ such that, for any $p > 0$ and T large enough

$$\mathbf{P}\{\hat{\theta}_T \geq c\} = \frac{e^{-TI(c)+H(a_c)}}{\sigma_c a_c \sqrt{2\pi T}} \left[1 + \sum_{k=1}^p \frac{b_{c,k}}{T^k} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right) \right] \quad (4.6)$$

with

$$a_c = \frac{c^2 - \theta^2}{2c}, \quad H(a_c) = -\frac{1}{2} \log \frac{(c + \theta)(3c - \theta)}{4c^2}, \quad (4.7)$$

and $\sigma_c^2 = L''(a_c) = -(2c)^{-1}$. The coefficients $b_{c,1}, b_{c,2}, \dots, b_{c,p}$ may be explicitly given as in Theorem 3.1. Furthermore, for $c > \theta/3$ with $c \neq 0$, there exists a sequence $(d_{c,k})$ such that, for any $p > 0$ and T large enough

$$\mathbf{P}\{\hat{\theta}_T \geq c\} = \frac{e^{-TI(c)+K(c)}}{\sigma^c a^c \sqrt{2\pi T}} \left[1 + \sum_{k=1}^p \frac{d_{c,k}}{T^k} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right) \right] \quad (4.8)$$

with $a^c = 2(c - \theta)$,

$$(\sigma^c)^2 = L''(a^c) = \frac{c^2}{2(2c - \theta)^3}, \quad K(c) = -\frac{1}{2} \log \frac{(c - \theta)(3c - \theta)}{4c^2}. \quad (4.9)$$

The coefficients $d_{c,1}, d_{c,2}, \dots, d_{c,p}$ may be explicitly calculated. For example,

$$d_{c,1} = \frac{2c^4 - c^3(19 + 3\theta) + c^2\theta(23 + \theta) - 12c\theta^2 + 2\theta^3}{4(c - \theta)(2c - \theta)(3c - \theta)^2}. \quad (4.10)$$

Finally, for $c = 0$, $p > 0$ and for T large enough

$$\mathbf{P}\{\hat{\theta}_T \geq 0\} = 2 \frac{e^{-TI(c)}}{\sqrt{2\pi T} \sqrt{-2\theta}} \left[1 + \sum_{k=1}^p \frac{(2k)!}{2^{2k} \theta^k T^k k!} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right) \right]. \quad (4.11)$$

R e m a r k. As $\mathbf{P}\{\hat{\theta}_T \geq 0\} = \mathbf{P}\{X_T^2 \geq T\}$ and X_T is Gaussian, (4.11) immediately follows from [13] (see relation (7.1), p. 193). It is easy to check that, for $c \rightarrow 0$, the main part of (4.8) and the first coefficient $d_{c,1}$ given by (4.10) coincide with the corresponding terms in (4.11).

Theorem 4.2. For $c = \theta/3$, there exists a sequence (d_k) such that, for any $p > 0$ and T large enough

$$\mathbf{P}\{\hat{\theta}_T \geq c\} = \frac{e^{-TI(c)} \Gamma(1/4)}{2\pi T^{1/4} a_\theta^{3/4} \sigma_\theta} \left[1 + \sum_{k=1}^{2p} \frac{d_k}{(\sqrt{T})^k} + \mathcal{O}\left(\frac{1}{T^p \sqrt{T}}\right) \right] \quad (4.12)$$

with $a_\theta = -4\theta/3$ and $\sigma_\theta^2 = L''(a_\theta) = -3/(2\theta)$. As before, the coefficients $d_1, d_2, \dots, d_{2p}$ may be explicitly calculated.

5. Log-likelihood ratio

If we wish to test $H_0: \theta = \theta_0$ versus $H_1: \theta = \theta_1$ for the Ornstein–Uhlenbeck process (1.1), then the most powerful test is based on the log-likelihood ratio (V_T) .

Lemma 5.1. Under the hypothesis H_0 , $(T^{-1}V_T)$ satisfies an LDP with good rate function

$$I(c) = \begin{cases} -\frac{1}{8} \frac{((\theta_0 - \theta_1)^2 + 4\theta_0 c)^2}{(\theta_0 - \theta_1 + 2c)(\theta_0^2 - \theta_1^2)} & \text{if } \frac{2c}{\theta_0 - \theta_1} > -1, \\ +\infty & \text{otherwise.} \end{cases} \quad (5.1)$$

The rate function I has a unique minimum in $c = -(\theta_0 - \theta_1)^2/(4\theta_0)$ which is the a.s. limit given in (1.5). For all $a \in \mathbf{R}$ such that $\theta_0^2 + (\theta_0^2 - \theta_1^2) \times a > 0$, set

$$\begin{aligned} L(a) &= \mathcal{L}\left(a(\theta_0 - \theta_1), -\frac{1}{2}a(\theta_0^2 - \theta_1^2)\right), \\ H(a) &= \mathcal{L}\left(a(\theta_0 - \theta_1), -\frac{1}{2}a(\theta_0^2 - \theta_1^2)\right). \end{aligned} \quad (5.2)$$

As in Section 2, the function L is steep. Therefore, we obtain an SLDP for (V_T) similar to Theorem 3.1.

Theorem 5.1. Under the hypothesis H_0 , $(T^{-1}V_T)$ satisfies an SLDP associated with L and H . More precisely, for all $c > -(\theta_0 - \theta_1)^2/(4\theta_0)$, there exists a sequence $(b_{c,k})$ such that, for any $p > 0$ and T large enough

$$\mathbf{P}\{V_T \geq cT\} = \frac{e^{-TI(c)+H(a_c)}}{\sigma_c a_c \sqrt{2\pi T}} \left[1 + \sum_{k=1}^p \frac{b_{c,k}}{T^k} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right) \right] \quad (5.3)$$

with a_c given by $L'(a_c) = c$ and

$$\sigma_c^2 = L''(a_c) = -\frac{(\theta_0 - \theta_1 + 2c)^3}{\theta_0^2 - \theta_1^2}. \quad (5.4)$$

The coefficients $b_{c,1}, b_{c,2}, \dots, b_{c,p}$ may be explicitly given as in Theorem 3.1.

6. Proofs of the main results

6.1. Proof of Theorem 3.1. Let L_T be the normalized c.g.f. of S_T .

For all $c > -1/(2\theta)$, set $\mathbf{P}\{S_T \geq cT\} = A_T B_T$ with

$$A_T = \exp\left[T(L_T(a_c) - ca_c)\right], \quad (6.1)$$

$$B_T = \mathbf{E}_T\left(\exp[-a_c(S_T - cT)] \mathbb{1}_{\{S_T \geq cT\}}\right), \quad (6.2)$$

where $\mathbf{E}_T$ is the expectation after the usual change of probability

$$\frac{d\mathbf{Q}_T}{d\mathbf{P}} = \exp(a_c S_T - T L_T(a_c)). \quad (6.3)$$

For all $a < \theta^2/2$, set $R_T(a) = \mathcal{R}_T(0, a)$. It follows from part ii) of Lemma 2.1 that $R_T(a_c) = \mathcal{O}(e^{-T/|c|})$. In addition, we also have from (2.1) together with (3.2) that

$$A_T = \exp[-TI(c) + H(a_c)] \left(1 + \mathcal{O}(e^{-T/|c|})\right). \quad (6.4)$$

It now remains to give an expansion of B_T which can be rewritten as

$$B_T = \mathbf{E}_T\left(\exp\left[-a_c \sigma_c \sqrt{T} U_T\right] \mathbb{1}_{\{U_T \geq 0\}}\right), \quad \text{where } U_T = \frac{S_T - cT}{\sigma_c \sqrt{T}}. \quad (6.5)$$

Lemma 6.1. For $c > -1/(2\theta)$, the distribution of U_T under $\mathbf{Q}_T$ converges, as T goes to infinity, to the $N(0, 1)$ distribution. Moreover, there exists a sequence (δ_k) such that, for any $p > 0$ and T large enough

$$B_T = \frac{1}{\sqrt{T}} \left(\sum_{k=0}^p \frac{\delta_k}{T^k} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right) \right). \quad (6.6)$$

The sequence (δ_k) only depends on the derivatives of L and H at point a_c . For example,

$$\delta_0 = \frac{1}{\sigma_c a_c \sqrt{2\pi}} \quad \text{and} \quad \delta_1 = \frac{-2c\delta_1(12\theta^4 c^4 + 12\theta^3 c^3 + 35\theta^2 c^2 + 4\theta c + 2)}{(4\theta^2 c^2 - 1)^2}.$$

Proof of Theorem 3.1. Relation (3.3) follows from the conjunction of (6.4) and (6.6), which completes the proof of Theorem 3.1.

6.2. Proof of Theorem 4.1. The proof is completely different from the previous one since the function L is steep for $\theta < c \leq \theta/2$ while this is no longer true when $c > \theta/2$. The point a_c , given by (4.7), belongs to Γ whenever $c < \theta/3$. First, if $\theta < c \leq \theta/3$, we prove (4.6) as (3.3) via the usual change of probability.

Next, if $c > \theta/3$, we use a slight modification of the strategy of time varying change of probability proposed in [10] and [8]. Let L_T be the normalized c.g.f. of $Z_T(c)$, where the parameter c is omitted in order to simplify the notation. There is a unique a_T , which belongs to Γ and converges to a^c as $T \rightarrow \infty$, solution of the equation

$$L'(a_T) + \frac{H'(a_T)}{T} = 0. \quad (6.7)$$

Set

$$\frac{d\mathbf{Q}_T}{d\mathbf{P}} = \exp(a_T Z_T(c) - T L_T(a_T)) \quad (6.8)$$

and denote by $\mathbf{E}_T$ the expectation under this new probability. We have the decomposition $\mathbf{P}\{\hat{\theta}_T \geq c\} = A_T B_T$ with

$$A_T = \exp[T L_T(a_T)], \quad (6.9)$$

$$B_T = \mathbf{E}_T \left(\exp[-a_T Z_T(c)] \mathbf{1}_{\{Z_T(c) \geq 0\}} \right). \quad (6.10)$$

It follows from the identity (6.7) together with (4.3) that

$$T(\rho(a_T) - (a_T + \theta)) = \frac{\theta^2 - c\theta + a_T c}{\rho(a_T)(\rho(a_T) + c)}. \quad (6.11)$$

Since $\rho(a_T) = \sqrt{\theta^2 + 2a_T c}$, we have $\lim_{T \rightarrow \infty} \rho(a_T) = 2c - \theta$ and (6.11) immediately implies

$$\lim_{T \rightarrow \infty} T(\rho(a_T) - (a_T + \theta)) = \frac{c - \theta}{3c - \theta}. \quad (6.12)$$

From (6.7), there exists a sequence (a_k) such that, for any $p > 0$ and T large enough

$$a_T = a^c + \sum_{k=1}^p \frac{a_k}{T^k} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right). \quad (6.13)$$

For example, by (6.12),

$$a_1 = -\frac{2c - \theta}{3c - \theta} \quad \text{and} \quad a_2 = -\frac{c(c^2 - 5\theta c + 2\theta^2)}{2(c - \theta)(3c - \theta)^3}.$$

Moreover, for all $a \in \Gamma$, set $R_T(a) = \mathcal{R}_T(a, -ca)$. By use of (4.3), relation (2.1) can be rewritten as

$$L_T(a) = L(a) + \frac{H(a)}{T} + \frac{1}{T} R_T(a) \quad (6.14)$$

with $a \in \Gamma$. Next, by part ii) of Lemma 2.1, the remainder $R_T(a_T) = \mathcal{O}(T e^{-2(2c-\theta)T})$. Thus, we obtain from (6.9) and (6.14) that

$$A_T = \exp[T L(a_T) + H(a_T)] \left(1 + \mathcal{O}(T e^{-2(2c-\theta)T}) \right). \quad (6.15)$$

On the one hand, it follows from (6.13) that there exists a sequence (α_k) such that, for any $p > 0$ and T large enough

$$T L(a_T) = T L(a^c) + \frac{1}{2} + \sum_{k=1}^p \frac{\alpha_k}{T^k} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right). \quad (6.16)$$

The sequence (α_k) only depends on (a_k) and on the derivatives of L at point a^c . For example $\alpha_1 = a_2 L'(a^c) + \frac{1}{2} a_1^2 L''(a^c)$ so that

$$\alpha_1 = \frac{c(2c^3 + c^2(1 - 3\theta) + \theta c(\theta - 5) + 2\theta^2)}{4(c - \theta)(2c - \theta)(3c - \theta)^2}.$$

On the other hand, we also have from (2.2) and (4.3) that

$$\exp[H(a_T)] = \sqrt{\frac{2T\rho(a_T)}{T(\rho(a_T) - (a_T + \theta))}}. \quad (6.17)$$

Hence, from (6.12) together with (6.13), there exists a sequence (β_k) such that, for any $p > 0$ and T large enough

$$\exp[H(a_T)] = \sqrt{T} \sqrt{\frac{2(2c - \theta)(3c - \theta)}{c - \theta}} \left(1 + \sum_{k=1}^p \frac{\beta_k}{T^k} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right) \right). \quad (6.18)$$

The sequence (β_k) can be explicitly given as (α_k) . For example,

$$\beta_1 = -\frac{c(c^2 - 3\theta c + \theta^2)}{(c - \theta)(2c - \theta)(3c - \theta)^2}.$$

Finally, from (6.15) together with (6.16) and (6.18), it follows that there exists a sequence (γ_k) such that, for any $p > 0$ and T large enough

$$\begin{aligned} A_T &= \exp[-TI(c)] \sqrt{eT} \sqrt{\frac{2(2c - \theta)(3c - \theta)}{c - \theta}} \\ &\times \left(1 + \sum_{k=1}^p \frac{\gamma_k}{T^k} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right) \right). \end{aligned} \quad (6.19)$$

The sequence (γ_k) only depends on (a_k) and on the derivatives of L at point a^c . For example, $\gamma_1 = \alpha_1 + \beta_1$ so that

$$\gamma_1 = \frac{c(2c^3 - 3c^2(1 + \theta) + \theta c(\theta + 7) - 2\theta^2)}{4(c - \theta)(2c - \theta)(3c - \theta)^2}.$$

For $c > \theta/3$, the following lemma gives the asymptotical behavior of the distribution of U_T and an expansion of B_T which can be rewritten as

$$B_T = \mathbf{E}_T(\exp[-a_T T U_T] \mathbb{1}_{U_T \geq 0}), \quad \text{where } U_T = \frac{Z_T(c)}{T}. \quad (6.20)$$

Lemma 6.2. i) *The distribution of U_T under $\mathbf{Q}_T$ converges, as T goes to infinity, to the distribution of $\gamma(N^2 - 1)$, where N is $N(0, 1)$ random variable and $\gamma = -L'(a^c) = (3c - \theta)/(2(2c - \theta))$, i.e., the limit of the characteristic function of U_T under $\mathbf{Q}_T$ is*

$$\Phi(u) = \frac{\exp(-i\gamma u)}{\sqrt{1 - 2i\gamma u}}. \quad (6.21)$$

ii) *There exists a sequence (δ_k) such that, for any $p > 0$ and T large enough*

$$B_T = \sum_{k=1}^p \frac{\delta_k}{T^k} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right). \quad (6.22)$$

The sequence (δ_k) only depends on the Taylor expansion of a_T at the neighborhood of a^c together with the derivatives of L at point a^c . For example,

$$\delta_1 = \frac{1}{a^c \gamma \sqrt{2\pi e}} \quad \text{and} \quad \delta_2 = \frac{\delta_1}{\gamma} \frac{-8c^3 + 8c^2\theta - 5c\theta^2 + \theta^3}{2(c-\theta)(2c-\theta)(3c-\theta)^2}.$$

R e m a r k. Part i) was previously proven in [14] (see Lemma 4.6, p. 17). Part ii) is not a consequence of i). It requires a more precise study of the convergence of Φ_T towards Φ given in Lemma 7.2 below.

P r o o f o f T h e o r e m 4.1. Relation (4.8) follows from the conjunction of (6.19) and (6.22), which completes the proof of Theorem 4.1.

6.3. Proof of Theorem 4.2. We follow the same approach as the one of Theorem 4.1. Assume that $c = \theta/3$ so that $a_c = a^c = a_\theta$ with $a_\theta = -4\theta/3$. There is a unique a_T , which belongs to Γ and converges to a_θ as $T \rightarrow \infty$, solution of the equation

$$L'(a_T) + \frac{H'(a_T)}{T} = 0. \quad (6.23)$$

From (2.2) together with (4.3), it is easy to see that

$$\lim_{T \rightarrow \infty} (\rho(a_T) - (a_T + \theta)) H'(a_T) = 1. \quad (6.24)$$

Moreover, a Taylor expansion around a_θ gives $L'(a_T) = (a_T - a_\theta)\sigma_\theta^2 + o(a_T - a_\theta)$ with $\sigma_\theta^2 = L''(a_\theta) = -3/(2\theta)$. Thus, we find from (6.23) together with (6.24)

$$\lim_{T \rightarrow \infty} T(a_T - a_\theta)^2 = \frac{1}{2\sigma_\theta^2}. \quad (6.25)$$

Next, as in Section 6.2, there exists a sequence (a_k) such that, for any $p > 0$ and T large enough

$$a_T = a_\theta + \sum_{k=1}^{2p} \frac{a_k}{(\sqrt{T})^k} + \mathcal{O}\left(\frac{1}{T^p \sqrt{T}}\right). \quad (6.26)$$

For example, $a_1 = -1/(\sigma_\theta \sqrt{2})$ and $a_2 = -\frac{1}{8}$. In addition, if we use the decomposition $\mathbf{P}\{\hat{\theta}_T \geq c\} = A_T B_T$ given by (6.9) and (6.10), we obtain as in (6.19) that, for any $p > 0$ and T large enough

$$\begin{aligned} A_T &= \exp[-TI(c)] (eT)^{1/4} \left(-\frac{\theta}{3}\right)^{1/4} \\ &\quad \times \left(1 + \sum_{k=1}^{2p} \frac{\gamma_k}{(\sqrt{T})^k} + \mathcal{O}\left(\frac{1}{T^p \sqrt{T}}\right)\right), \end{aligned} \quad (6.27)$$

where the sequence (γ_k) may be explicitly calculated. For $c = \theta/3$, it now remains to give an expansion of B_T which can be rewritten as

$$B_T = \mathbf{E}_T \left(\exp[-a_T \sqrt{T} U_T] \mathbf{1}_{\{U_T \geq 0\}} \right), \quad \text{where } U_T = \frac{Z_T(c)}{\sqrt{T}}. \quad (6.28)$$

Lemma 6.3. i) *The distribution of U_T under $\mathbf{Q}_T$ converges, as T goes to infinity, to the distribution of $\sigma_\theta N_1 + \eta_\theta(N_2^2 - 1)$, where N_1 and N_2 are independent $N(0, 1)$ random variables and $\sigma_\theta^2 = L''(a_\theta) = -3/(2\theta)$ and $\eta_\theta = \sigma_\theta/\sqrt{2}$, i.e., the limit of the characteristic function of U_T under $\mathbf{Q}_T$ is*

$$\Phi(u) = \frac{\exp(-i\eta_\theta u - \sigma_\theta^2 u^2/2)}{\sqrt{1 - 2i\eta_\theta u}}. \quad (6.29)$$

ii) *For any $p > 0$ and T large enough*

$$B_T = \sum_{k=1}^{2p} \frac{\delta_k}{(\sqrt{T})^k} + \mathcal{O}\left(\frac{1}{T^p \sqrt{T}}\right), \quad (6.30)$$

where the sequence (δ_k) may be explicitly calculated. For example,

$$\delta_1 = \frac{1}{4\pi a_\theta \eta_\theta} e^{-1/4} \Gamma\left(\frac{1}{4}\right).$$

Proof of Theorem 4.2. Relation (4.12) follows from the conjunction of (6.27) and (6.30), which completes the proof of Theorem 4.2.

6.4. Proof of Theorem 5.1. The proof follows exactly the same lines as the one of Theorem 3.1 since the function L associated with the log-likelihood ratio (V_T) is steep.

7. Proofs of lemmas

7.1. Proof of Lemma 2.2. i) We refer to Janson [17, Chapters 2 and 6]. The two random variables $Y_1 = X_T^2/2$ and $Y_2 = \int_0^T X_t^2 dt$ are in the chaos $H^{(2)} \oplus H^{(0)}$. The operators B_1 and B_2 associated to their bilinear forms are positive, trace class and their traces are expectations: $\text{tr} B_1 = \mathbf{E}Y_1$ and $\text{tr} B_2 = \mathbf{E}Y_2$. By linearity, for any $(a, b) \in \mathbf{R}^2$, $a(Y_1 - \mathbf{E}Y_1) + b(Y_2 - \mathbf{E}Y_2)$ belongs to $H^{(2)}$. Consequently, from Theorem 6.1 of [17, p. 78], we have the decomposition

$$a(Y_1 - \mathbf{E}Y_1) + b(Y_2 - \mathbf{E}Y_2) = \sum_{j=1}^{\infty} \lambda_j^T (\varepsilon_j^2 - 1), \quad (7.1)$$

where (ε_j) are independent $N(0, 1)$ random variables and (λ_j^T) are the eigenvalues of $aB_1 + bB_2$. Since this operator is trace class, part i) of Lemma 2.2 follows from (7.1).

ii) The spectrum $\sigma(B_2) \subset [0, \theta^{-2}]$ (see [8]) and $\mathbf{E}X_T^2/2$ is uniformly bounded in T .

iii) From (1.6), (1.7) and (2.5), the normalized c.g.f. of $\mathcal{L}_T(a, b)$ in α is $\mathcal{L}_T(\alpha a, \alpha b)$. From part i), it can be rewritten as

$$\mathcal{L}_T(\alpha a, \alpha b) = -\frac{\alpha a}{2} - \frac{1}{2} \langle \nu_T, \Psi_\alpha \rangle, \quad (7.2)$$

where ν_T is given by (2.6) and $\Psi_\alpha(x) = \log(1 - 2\alpha x)$ (notice that $\Psi_\alpha \in \mathcal{F}$). From Lemma 2.1, we already know that

$$\lim_{T \rightarrow \infty} \mathcal{L}_T(\alpha a, \alpha b) = \mathcal{L}(\alpha a, \alpha b) = -\frac{1}{2} (\alpha a + \theta + \rho(\alpha b)) \quad (7.3)$$

for α in some interval $[-\alpha_0, \alpha_0]$ depending on a and b , with $\alpha_0 > 0$. Thus, it immediately follows from (7.2) and (7.3) that $\lim_{T \rightarrow \infty} \langle \nu_T, \Psi_\alpha \rangle = \theta + \rho(\alpha b)$. Since ν is defined by $\langle \nu, h \rangle = 1/(2\pi) \int_{\mathbf{R}} h(bg(x)) dx$, where h is any continuous function with compact support, an easy integration by parts gives $\langle \nu, \Psi_\alpha \rangle = \theta + \rho(\alpha b)$ which proves that

$$\lim_{T \rightarrow \infty} \langle \nu_T, \Psi_\alpha \rangle = \langle \nu, \Psi_\alpha \rangle \quad (7.4)$$

for every $\alpha \in [-\alpha_0, \alpha_0]$. By use of the above part ii) together with a slight modification of Lemma 9 of [4], we arrive from (7.4) to the convergence of ν_T towards ν , which completes the proof of Lemma 2.2.

7.2. Proof of Lemma 6.1. If Φ_T is the characteristic function of U_T under $\mathbf{Q}_T$, (6.3) immediately implies

$$\Phi_T(u) = \exp \left[-\frac{i u \sqrt{T} c}{\sigma_c} + T \left(L_T \left(a_c + \frac{i u}{\sigma_c \sqrt{T}} \right) - L_T(a_c) \right) \right], \quad (7.5)$$

so that

$$|\Phi_T(u)|^2 = \prod_{j=1}^{\infty} \left(1 + \frac{4u^2(\lambda_j^T)^2}{\sigma_c^2 T (1 - 2a_c \lambda_j^T)^2} \right)^{-1/2}. \quad (7.6)$$

Choose $\varepsilon > 0$ such that $1 - 2a_c \varepsilon > 0$ and let $q_T = \text{card}\{\lambda_j^T \mid \lambda_j^T > \varepsilon\}$. Then, by Lemma 2.2 part iii), it exists some positive constant η , only depending on ε , such that

$$\liminf_{T \rightarrow \infty} \frac{q_T}{T} \geq \eta. \quad (7.7)$$

Thus, it follows from (7.6) together with (7.7) that, for T large enough

$$|\Phi_T(u)|^2 \leq \left(1 + \frac{\xi u^2}{T} \right)^{-\eta T/2} \quad (7.8)$$

with $\xi > 0$. Thereby, for T large enough, $\Phi_T \in L^2(\mathbf{R})$ and we can use the Parseval formula in (6.5) to get

$$B_T = \frac{1}{2\pi a_c \sigma_c \sqrt{T}} \int_{\mathbf{R}} \left(1 + \frac{i u}{a_c \sigma_c \sqrt{T}} \right)^{-1} \Phi_T(u) du. \quad (7.9)$$

For some positive constant s , set $s_T = sT^{1/6}$. We separate $B_T = C_T + D_T$, where

$$C_T = \frac{1}{2\pi a_c \sigma_c \sqrt{T}} \int_{|u| \leq s_T} \left(1 + \frac{i u}{a_c \sigma_c \sqrt{T}} \right)^{-1} \Phi_T(u) du, \quad (7.10)$$

$$D_T = \frac{1}{2\pi a_c \sigma_c \sqrt{T}} \int_{|u| > s_T} \left(1 + \frac{i u}{a_c \sigma_c \sqrt{T}} \right)^{-1} \Phi_T(u) du. \quad (7.11)$$

On the one hand, we find from (7.8) that

$$|D_T| = O \left(\left(1 + \frac{\xi s_T^2}{T} \right)^{-\eta T/4} \right) \quad (7.12)$$

so that $|D_T| = \mathcal{O}(e^{-\mu T^{1/3}})$ with $\mu > 0$. On the other hand, it follows from (2.3) that for any $k \in \mathbb{N}$, $R_T^{(k)}(a_c) = \mathcal{O}(T^k e^{-T/|c|})$. Then, we get using (3.2) and (2.1)

$$L_T^{(k)}(a_c) = L^{(k)}(a_c) + \frac{H^{(k)}(a_c)}{T} + \mathcal{O}(T^k e^{-T/|c|}). \quad (7.13)$$

Consequently, via (7.5) together with (7.13), we can prove the following Taylor expansion for Φ_T . Similar expansion was established in the i.i.d. case by Cramer [7] and Esseen [12].

Lemma 7.1. *For any $p > 0$, there exist integers $q(p)$, $r(p)$ and a sequence $(\varphi_{k,l})$ independent of p , such that, for T large enough*

$$\begin{aligned} \Phi_T(u) &= \exp\left(-\frac{u^2}{2}\right) \\ &\times \left[1 + \frac{1}{\sqrt{T}} \sum_{k=0}^{2p} \sum_{l=k+1}^{q(p)} \frac{\varphi_{k,l} u^l}{(\sqrt{T})^k} + \mathcal{O}\left(\frac{\max(1, |u|^{r(p)})}{T^{p+1}}\right)\right] \end{aligned} \quad (7.14)$$

and the remainder $\mathcal{O}$ is uniform as soon as $|u| = \mathcal{O}(T^{1/6})$.

P r o o f. From (7.5) and (7.13), we have

$$\begin{aligned} \log \Phi_T(u) &= -\frac{u^2}{2} + T \sum_{k=3}^{2p+3} \left(\frac{i u}{\sigma_c \sqrt{T}}\right)^k \frac{L^{(k)}(a_c)}{k!} + \sum_{k=1}^{2p+1} \left(\frac{i u}{\sigma_c \sqrt{T}}\right)^k \frac{H^{(k)}(a_c)}{k!} \\ &+ \mathcal{O}\left(\frac{\max(1, u^{2p+4})}{T^{p+1}}\right). \end{aligned} \quad (7.15)$$

Thus, we follow the same approach as Cramer (see [7, Lemma 2, p. 72]) remarking that in the range $|u| = \mathcal{O}(T^{1/6})$, the quantity $u^l/(\sqrt{T})^k$ remains bounded in (7.14). Lemma 7.1 is proved.

P r o o f o f L e m m a 6.1. Relation (6.6) follows from (7.10) and (7.14) together with standard calculus on the $N(0, 1)$ distribution.

7.3. Proof of Lemma 6.2. Let Φ_T be the characteristic function of U_T under $\mathbf{Q}_T$. We have from (6.8)

$$\Phi_T(u) = \exp \left[T \left(L_T \left(a_T + \frac{i u}{T} \right) - L_T(a_T) \right) \right], \quad (7.16)$$

so that

$$|\Phi_T(u)|^2 = \prod_{j=1}^{\infty} \left(1 + \frac{4u^2(\lambda_j^T)^2}{T^2(1 - 2a_T\lambda_j^T)^2} \right)^{-1/2}. \quad (7.17)$$

As in (7.8), it follows from Lemma 2.2, part iii), that, for some positive constants η, ξ and for T large enough

$$|\Phi_T(u)|^2 \leq \left(1 + \frac{\xi u^2}{T^2} \right)^{-\eta T}. \quad (7.18)$$

Thereby, for T large enough, $\Phi_T \in L^2(\mathbf{R})$ and we can use the Parseval formula in (6.20) to obtain that

$$B_T = \frac{1}{2\pi T a_T} \int_{\mathbf{R}} \left(1 + \frac{i u}{T a_T}\right)^{-1} \Phi_T(u) du. \quad (7.19)$$

Let $s_T > 0$ be such that $\sqrt{T} = o(s_T)$ as $T \rightarrow \infty$. We split B_T into two terms, $B_T = C_T + D_T$, where

$$C_T = \frac{1}{2\pi T a_T} \int_{|u| \leq s_T} \left(1 + \frac{i u}{T a_T}\right)^{-1} \Phi_T(u) du, \quad (7.20)$$

$$D_T = \frac{1}{2\pi T a_T} \int_{|u| > s_T} \left(1 + \frac{i u}{T a_T}\right)^{-1} \Phi_T(u) du. \quad (7.21)$$

First, we find as in (7.12) that, if $s_T = o(T)$, $|D_T| = \mathcal{O}(\exp(-\mu s_T^2/T))$ with $\mu > 0$. It now remains to precisely evaluate C_T via the following Taylor expansion for Φ_T .

Lemma 7.2. *For any $p > 0$, there exist integers $q(p)$, $r(p)$, $s(p)$ and a sequence $(\varphi_{k,l,m})$ independent of p , such that, for T large enough*

$$\begin{aligned} \Phi_T(u) &= \Phi(u) \exp\left(-\frac{\sigma^2 u^2}{2T}\right) \\ &\times \left[1 + \sum_{k=1}^p \sum_{l=k+1}^{q(p)} \sum_{m=0}^{r(p)} \frac{\varphi_{k,l,m} u^l}{T^k (1 - 2i\gamma u)^m} + \mathcal{O}\left(\frac{\max(1, |u|^{s(p)})}{T^{p+1}}\right)\right], \end{aligned}$$

where Φ is given by (6.21),

$$\gamma = -L'(a^c) = \frac{3c - \theta}{2(2c - \theta)} \quad \text{and} \quad \sigma^2 = L''(a^c) = \frac{c^2}{2(2c - \theta)^3}.$$

Moreover, the remainder $\mathcal{O}$ is uniform as soon as $|u| = o(T^{2/3})$.

Remark. One can see in this asymptotic expansion the limit χ^2 distribution Φ together with an independent centered Gaussian distribution with small variance σ^2/T .

Proof. From (6.14) together with (7.16)

$$\begin{aligned} \Phi_T(u) &= \exp\left[T\left(L\left(a_T + \frac{i u}{T}\right) - L(a_T)\right)\right] \\ &\times \exp\left[H\left(a_T + \frac{i u}{T}\right) - H(a_T)\right] (1 + \mathcal{O}(e^{-\xi T})) \end{aligned}$$

with $\xi > 0$. On the one hand, (4.5) immediately implies

$$\begin{aligned} T\left(L\left(a_T + \frac{i u}{T}\right) - L(a_T)\right) &= -\frac{i u}{2} - \frac{T}{2} \rho(a_T) \\ &\times \left(\left(1 + \frac{i u b_T}{T}\right)^{1/2} - 1\right), \end{aligned} \quad (7.22)$$

where $b_T = 2c(\rho(a_T))^{-2}$. Consequently, for any $p \geq 2$

$$\begin{aligned} \exp \left[T \left(L \left(a_T + \frac{iu}{T} \right) - L(a_T) \right) \right] &= \exp \left(-\frac{iu}{4} (2 + \rho(a_T) b_T) \right) \\ &\times \exp \left(-\frac{T}{2} \rho(a_T) \sum_{k=2}^p l_k \left(\frac{iub_T}{T} \right)^k \right) \left(1 + \mathcal{O} \left(\frac{|u|^{p+1}}{T^{p+1}} \right) \right), \end{aligned} \quad (7.23)$$

where $l_k = (-1)^{k-1} (2k)! / ((2k-1)(2^k k!)^2)$. On the other hand, we obtain from (2.2)

$$\begin{aligned} \exp \left[H \left(a_T + \frac{iu}{T} \right) - H(a_T) \right] \\ = \sqrt{\frac{\rho(a_T) - (a_T + \theta)}{\rho(a_T) - (a_T + iu/T + \theta)(1 + iub_T/T)^{-1/2}}}. \end{aligned} \quad (7.24)$$

If $c_T = T(\rho(a_T) - (a_T + \theta))$ and $d_T(u) = 1 - iu/c_T + (a_T + \theta)iub_T/(2c_T)$, we have for any $p \geq 2$

$$\begin{aligned} \exp \left[H \left(a_T + \frac{iu}{T} \right) - H(a_T) \right] \\ = \frac{1}{\sqrt{d_T(u)}} \left(1 - \frac{u^2 b_T}{2T c_T d_T(u)} - \frac{T(a_T + \theta + iuT^{-1})}{c_T d_T(u)} \right. \\ \left. \times \left[\sum_{k=2}^p h_k \left(\frac{iub_T}{T} \right)^k + \mathcal{O} \left(\frac{|u|^{p+1}}{T^{p+1}} \right) \right] \right)^{-1/2} \end{aligned} \quad (7.25)$$

with $h_k = (-1)^k (2k)! / (2^k k!)^2$. As T goes to infinity, the limits of a_T , b_T , c_T and $d_T(u)$ are a^c , $2c/(2c - \theta)^2$, $(c - \theta)/(3c - \theta)$ and $1 - 2i\gamma u$, respectively. Therefore, we find by (7.23) together with (7.25), the pointwise convergence

$$\lim_{T \rightarrow \infty} \Phi_T(u) = \Phi(u) = \frac{\exp(-i\gamma u)}{\sqrt{1 - 2i\gamma u}} \quad (7.26)$$

which achieves the proof of the first part of Lemma 6.2. Finally, after tedious calculus, we prove Lemma 7.2 via a Taylor expansion of the exponential in (7.23) together with a Taylor expansion of the square root in (7.25).

E n d o f t h e p r o o f o f L e m m a 6.2. From (7.20) and the above expansion of Φ_T , we have for T large enough

$$\begin{aligned} 2\pi T a_T C_T &= \int_{|u| \leq s_T} \Phi(u) \exp \left(-\frac{\sigma^2 u^2}{2T} \right) \left[1 + \mathcal{O} \left(\frac{\max(1, |u|^{s(p)})}{T^{p+1}} \right) \right] du \\ &+ \sum_{k=1}^p \sum_{l=k+1}^{q(p)} \sum_{m=0}^{r(p)} \psi_{k,l,m} \int_{|u| \leq s_T} \Phi(u) \exp \left(-\frac{\sigma^2 u^2}{2T} \right) \\ &\quad \times \frac{u^l}{T^k (1 - 2i\gamma u)^m} du, \end{aligned} \quad (7.27)$$

where the sequence $(\varphi_{k,l,m})$ is replaced by $(\psi_{k,l,m})$ due to the factor preceding Φ_T in (7.20). Furthermore, for all $u \in \mathbf{R}$, $|\Phi(u)| \leq 1$ and

$$\int_{|u| > s_T} \exp\left(-\frac{\sigma^2 u^2}{2T}\right) du = \mathcal{O}\left(\exp\left(-\frac{\sigma^2 s_T^2}{2T}\right)\right).$$

Thus, we may change in (7.27) all the integrals by integrals over $\mathbf{R}$ at the cost of $\mathcal{O}(\exp(-\mu s_T^2/T))$ with $\mu > 0$. We complete the proof of (6.22) via the following lemma which gives the values of integrals of the type

$$\int_{\mathbf{R}} \exp\left(-iu\gamma - \frac{\sigma^2 u^2}{2T}\right) \frac{u^\beta}{(1-2i\gamma u)^\alpha} du.$$

Let f_α be the density of the gamma distribution with parameters α and $\frac{1}{2}$,

$$f_\alpha(x) = \begin{cases} \exp\left(-\frac{x}{2}\right) \frac{x^{\alpha-1}}{2^\alpha \Gamma(\alpha)} & \text{if } x > 0, \\ 0 & \text{otherwise.} \end{cases} \quad (7.28)$$

For any $p > 0$ and $0 \leq k \leq p$, set

$$v_k(\alpha, \beta) = \frac{2\pi\sigma^{2k}i^\beta}{\gamma^{2k+\beta+1}2^k k!} f_\alpha^{(2k+\beta)}(1). \quad (7.29)$$

Lemma 7.3. *For any $p > 0$, we have*

$$\begin{aligned} \int_{\mathbf{R}} \exp\left(-iu\gamma - \frac{\sigma^2 u^2}{2T}\right) \frac{u^\beta}{(1-2i\gamma u)^\alpha} du \\ = \sum_{k=0}^p \frac{v_k(\alpha, \beta)}{T^k} + \mathcal{O}\left(\frac{1}{T^{p+1}}\right). \end{aligned} \quad (7.30)$$

Proof. Let $\hat{f}_\alpha$ be the characteristic function of f_α , $\hat{f}_\alpha(u) = 1/(1-2iu)^\alpha$. Denote by N_τ the Gaussian kernel of variance τ . First, we notice that

$$\int_{\mathbf{R}} \exp\left(-iv\xi - \frac{\tau v^2}{2}\right) v^\beta \hat{f}_\alpha(v) dv = 2\pi i^\beta f_\alpha * N_\tau^{(\beta)}(\xi). \quad (7.31)$$

It is rather easy to see that, for every $p > 0$

$$f_\alpha * N_\tau^{(\beta)}(\xi) = \sum_{k=0}^p \frac{\tau^k}{2^k k!} f_\alpha^{(2k+\beta)}(\xi) + \mathcal{O}(\tau^{p+1}). \quad (7.32)$$

For the sake of completeness, let us prove (7.32). We start with a localization

$$\left| f_\alpha * N_\tau^{(\beta)}(\xi) - \int_{|x| \leq \delta} f_\alpha(\xi - x) N_\tau^{(\beta)}(x) dx \right| \leq \sup_{|x| > \delta} |N_\tau^{(\beta)}(x)|$$

with $0 < \delta < \xi$. First, this supremum is $\mathcal{O}(\exp(-\mu_1 \tau^{-1}))$ with $\mu_1 > 0$. Next, the first term is easily integrated by parts since

$$\int_{|x| \leq \delta} f_\alpha(\xi - x) N_\tau^{(\beta)}(x) dx = \int_{|x| \leq \delta} f_\alpha^{(\beta)}(\xi - x) N_\tau(x) dx + \mathcal{O}(\exp(-\mu_2 \tau^{-1}))$$

with $\mu_2 > 0$. Furthermore, as the function $f_\alpha \in \mathcal{C}^\infty$ in $[\xi - \delta, \xi + \delta]$, we have the Taylor expansion

$$f_\alpha^{(\beta)}(\xi - x) = \sum_{k=0}^{2p+1} \frac{(-x)^k}{k!} f_\alpha^{(\beta+k)}(\xi) + \mathcal{O}(x^{2p+2})$$

for every $x \in [-\delta, +\delta]$. This yields

$$\begin{aligned} \int_{|x| \leq \delta} f_\alpha(\xi - x) N_\tau^{(\beta)}(x) dx &= \sum_{k=0}^p f_\alpha^{(2k+\beta)}(\xi) \frac{1}{(2k)!} \int_{|x| \leq \delta} x^{2k} N_\tau(x) dx \\ &\quad + \mathcal{O}\left(\int_{|x| \leq \delta} x^{2p+2} N_\tau(x) dx\right). \end{aligned}$$

Therefore, if we remove the localization whose cost is $\mathcal{O}(\exp(-\mu_3 \tau^{-1}))$, we find that

$$f_\alpha * N_\tau^{(\beta)}(\xi) = \sum_{k=0}^p f_\alpha^{(2k+\beta)}(\xi) \frac{1}{(2k)!} \int_{\mathbf{R}} x^{2k} N_\tau(x) dx + \mathcal{O}\left(\int_{\mathbf{R}} x^{2p+2} N_\tau(x) dx\right)$$

which immediately leads to (7.32). Finally, by a change of variables in (7.31), we obtain

$$\int_{\mathbf{R}} \exp\left(-iu\gamma - \frac{\sigma^2 u^2}{2T}\right) \frac{u^\beta}{(1 - 2i\gamma u)^\alpha} du = \frac{2\pi(-i)^\beta}{\gamma^{\beta+1}} f_\alpha * N_\tau^{(\beta)}(1) \quad (7.33)$$

with $\tau = \sigma^2/(T\gamma^2)$, which completes the proof of Lemma 7.3.

7.4. Proof of Lemma 6.3. Let Φ_T be the characteristic function of U_T under $\mathbf{Q}_T$ given by (6.8),

$$\Phi_T(u) = \exp\left[T\left(L_T\left(a_T + \frac{iu}{\sqrt{T}}\right) - L_T(a_T)\right)\right]. \quad (7.34)$$

We only prove the pointwise convergence of Φ_T given in (6.29) as the proof of the Taylor expansion (6.30) follows essentially the same arguments as those of Section 7.3. From the definition (4.5) of L , we have

$$\lim_{T \rightarrow \infty} T\left(L\left(a_T + \frac{iu}{\sqrt{T}}\right) - L(a_T)\right) = -i\eta_\theta u - \frac{\sigma_\theta^2 u^2}{2}. \quad (7.35)$$

Moreover, we also have from the definition (2.2) of H

$$\lim_{T \rightarrow \infty} \exp\left[H\left(a_T + \frac{iu}{\sqrt{T}}\right) - H(a_T)\right] = \frac{1}{\sqrt{1 - 2i\eta_\theta u}}. \quad (7.36)$$

Therefore, the pointwise convergence (6.29) immediately follows from (2.1), (7.35) and (7.36). The first term in (6.30) is $\delta_1 = (2\pi a_\theta)^{-1} \int_{\mathbf{R}} \Phi(u) du$. By a change of variables together with the fact that $2\eta_\theta^2 = \sigma_\theta^2$, we find that

$$\delta_1 = \frac{1}{2\pi a_\theta \eta_\theta} \int_{\mathbf{R}} \frac{1}{\sqrt{1 - 2iu}} \exp(-(u^2 + iu)) du.$$

Finally, via a contour integral for the gamma function, we obtain

$$\delta_1 = \frac{1}{4\pi a_\theta \eta_\theta} \exp\left(-\frac{1}{4}\right) \Gamma\left(\frac{1}{4}\right)$$

which completes the proof of Lemma 6.3.
